# Main topic for discussion

#BulletPoints<3 #IEC61400-3

Trivial to say it: wind, waves, water level and currents vary in time and space, with scales covering several orders of magnitudes.

We typically have, at hand for design work, a variety of wind information:

- What datasets for what type of analysis ?
- How do they fit together in the Design Basis ?

Source	Spatial resolution		Temporal resolution			
	Horiz.	Vert.	Averaging.	Frequency (step)	Sampling.	Length.
Cup measurements.	1 m	1 m	10 min	1 s	10 min	1 year
LiDAR measurements.	10 m	10 m	10 min	1 s	10 min	1 year
Mesoscale models	1 km	10 m	10min to 1h	1-10s	1 h	10 year
Reanalysis models	10 km	100 m	1 h	1 min	1 h	10-100 year

## #ModelsNestedInModelsNestedInModels

RUNE project, DTU Wind Energy, Final Report. Chapter 3.

Mesoscale Models

Atmosphere.

Use Reanalysis as input.

Refined landuse/orography.

1-10 km

Surface + [10,20,...,250

Hourly.

10-30 years.

Commercial product.

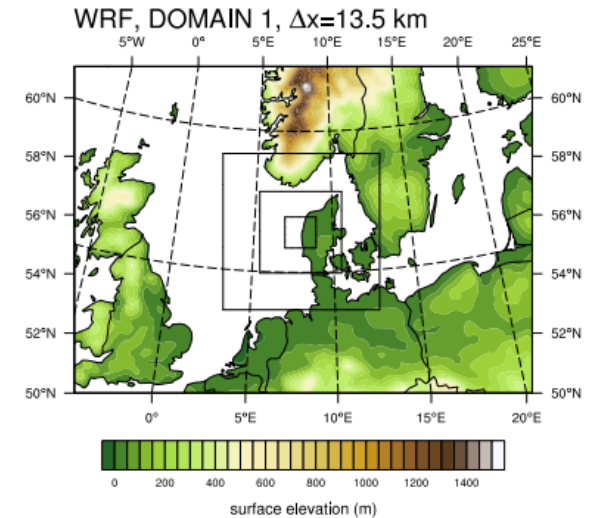

Figure 3. Surface elevation (m) of the outer domain with the location four nested model domains indicated.

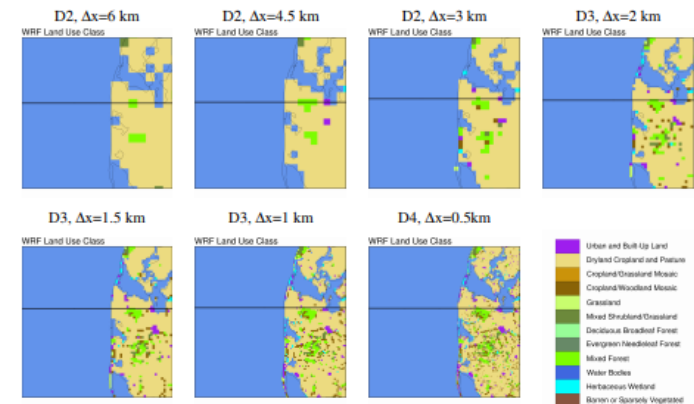

Figure 4. Land use classes derived from the CORINE dataset in the region of the fourth domain. The solid line shows the location of the cross section analyzed in Sec. 6.3.

Normal Wind Conditions = Wind distribution + Shear exponent + Free Stream  $T/I$   
Not in this presentation.

State of the Art:

- measurements
- + long-term correction (reanalysis/mesoscale)
- + spatial extrapolation.

Typical problem:

- I have some long-term corrected wind distribution at height  $h$  at location  $A$ , while the wind farm is at location  $B$ .
- I can choose between several model products, for ex:
  - A map over average 20-years wind speeds, at  $h$ , which covers  $A$  and  $B$ .
  - A time series at location  $A$ , and one at location  $B$ .
- The spatial resolution of both products vary between the suppliers.
- What product should I choose ?

# Normal Sea State

#

We now have two wind datasets, that need be used for design:

- The Normal Wind Conditions at hub height: meso- to micro scale information.
- The wind field used for driving the spectral wave model: synoptic wind information.

Method:

- 1) When both wind distributions can be fitted using Weibull: scale the reanalysis wind field so that it matches the one from the wind resource.
- 2) Derive wind/wave correlation using wind time series from 1).

In effect, the wind speed time series used for deriving the correlation has a much lower fidelity than the one from the wind resource. However, this is usually acceptable as the most important is to preserve the correlation between wind and waves.

Caveats:

- What if the distributions are not well represented by Weibull ?
- What if the wind roses show a significant difference ?
- What if the hub height is only mildly correlated with the surface wind ?
- Generally: the low-fidelity of the scaled reanalysis time series.

# Normal Sea State

#

Note on the importance of the landmask spatial resolution of the reanalysis dataset:

*CSFR*

*CSFR v2*

## Caveats:

- What if the distributions are not well represented by Weibull ?
- What if the wind roses show a significant difference ?
- Generally: the low-fidelity of the scaled reanalysis time series, for any other use..

So how could this be improved ? By driving the wave model with a wind dataset which contains both an good fidelity 10m and 100m wind. For instance:

- The best-reanalysis-dataset-ever-so-far: ERA5. It contains both a quality 10m and a quality 100m wind time series that require less adjustments than other reanalysis.
- Or, use a mesoscale model (WRF) wind dataset to drive the spectral wave model.

## Caveats:

- Need make sure that there is no loss of fidelity of the wave model (!). Only part of the wave spectrum is driven by local winds, therefore wave model nesting is crucial for success. Calibration is always expected in any case.
- With WRF: one mesoscale time series is (of course) not enough. Large custom-made domains are needed. Therefore this is a more expensive option.

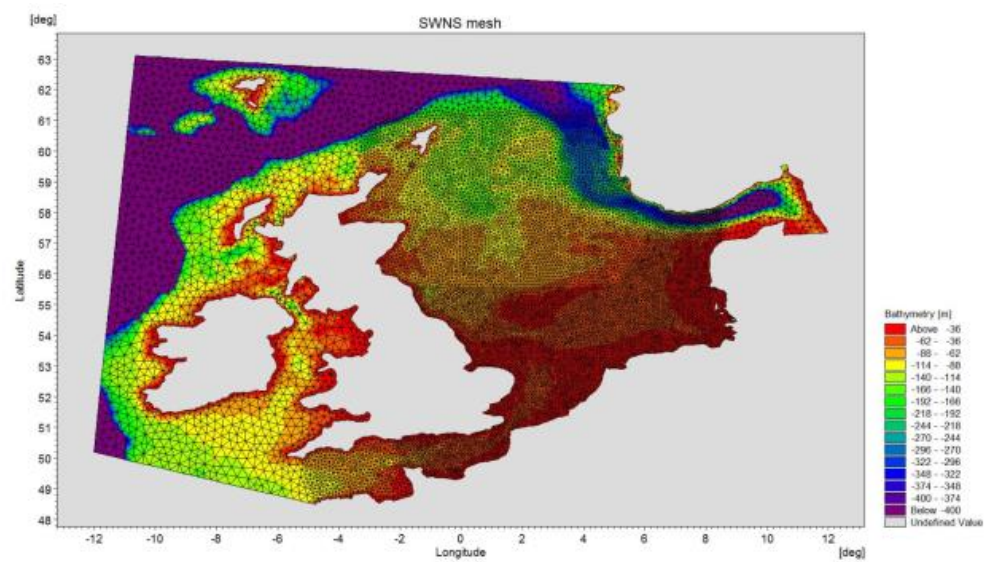

Figure 5.4 Domain of the regional DHI North Sea wave model,  $SW_{NS}$

Figure 5.35 Zoom at the HK area from the local mesh

# Extreme Sea State

Assessment of extreme loads from wind and waves. Here, extreme 10-minute wind speed need be combined with extreme 3-hour seastate. Reanalysis data is not an option for assessing the 10-minute extreme wind.

Extreme wind estimate can be made using WRF, but the results need be corrected. Here again, increasing the spatial resolution may not help.

## 9.2 Offline CFSR-MIKE modeling 15 storms: assessment of CFSR wind forcing

The calibrated MIKE 21 SW model was also forced with the global CFSR wind field (corrected for atmospheric stability, see section 5.5.1) for the 15 calibration storms. The results are presented in the following sections. It should be noted that the wave model was calibrated to the WRF wind field (see section 5.6) and not the CFSR wind field, however a comparison was still made to assess the impact of the different wind fields.

The results from the model test are presented in Fig. 49 to 50. The significant wave height produced from the CFSR wind field forced MIKE 21 SW model produced a reasonable representation of the observations for the North Sea and western Danish Coastline. From the Taylor diagrams on the left hand side of Fig. 50 and Fig. 51, a comparison to the final calibration of the WRF forced wave model is suggested to outperform the other. Note that the full storm list cannot be compared as CFSR forced model was only run for the 15 calibration storms, and thus comparisons are limited, however with these results there is no strong evidence of significant differences on wave modelling when using CFSR reanalysis or WRF downscaling.

### Project report

The project has delivered all planned deliverables in time. Though some of the planned deliverables have been merged into one due to the overlapping content and relevance between them. All deliverables have been presented to energinet.dk in Interim report format. The following list is an overview of the deliverables with the references included.

D1.1: The offline coupling system and the online coupling system (Interim report I) Only the technical reports in the original Interim report are provided. The description of the work progress and financial budget as in the original report can be found with energinet.dk)

D1.2: Implementation of wave stress in the atmospheric model WRF (Access Interim report V here)

D1.3: MIKE 3 coupling added value (Access Interim report VI here)

D1.4+D1.9: Database of simulated storms. (Available at [www.xwiwa.dk/data](http://www.xwiwa.dk/data))

D1.5: Atlas of the 50-year return wind at hub height for the Danish coastal zone. (Available at [www.xwiwa.dk/data](http://www.xwiwa.dk/data))

D1.6: Journal paper about the improved atmospheric modeling of storm cases (Access journals here)

D1.7: Journal paper about the sensitivity of the modeling on the resolution

The black point represents the observations. Scatter plot of the modelled significant wave height with forcing from the global CFSR wind field for the 15 calibration storms between Nov-1999 and Apr-2012 (right panel, corresponding to red point in Taylor diagram).

# Severe Sea State

#

Here, we estimate, for normal wind conditions (for instance 6 m/s), what the extreme 3-hour seastate is.

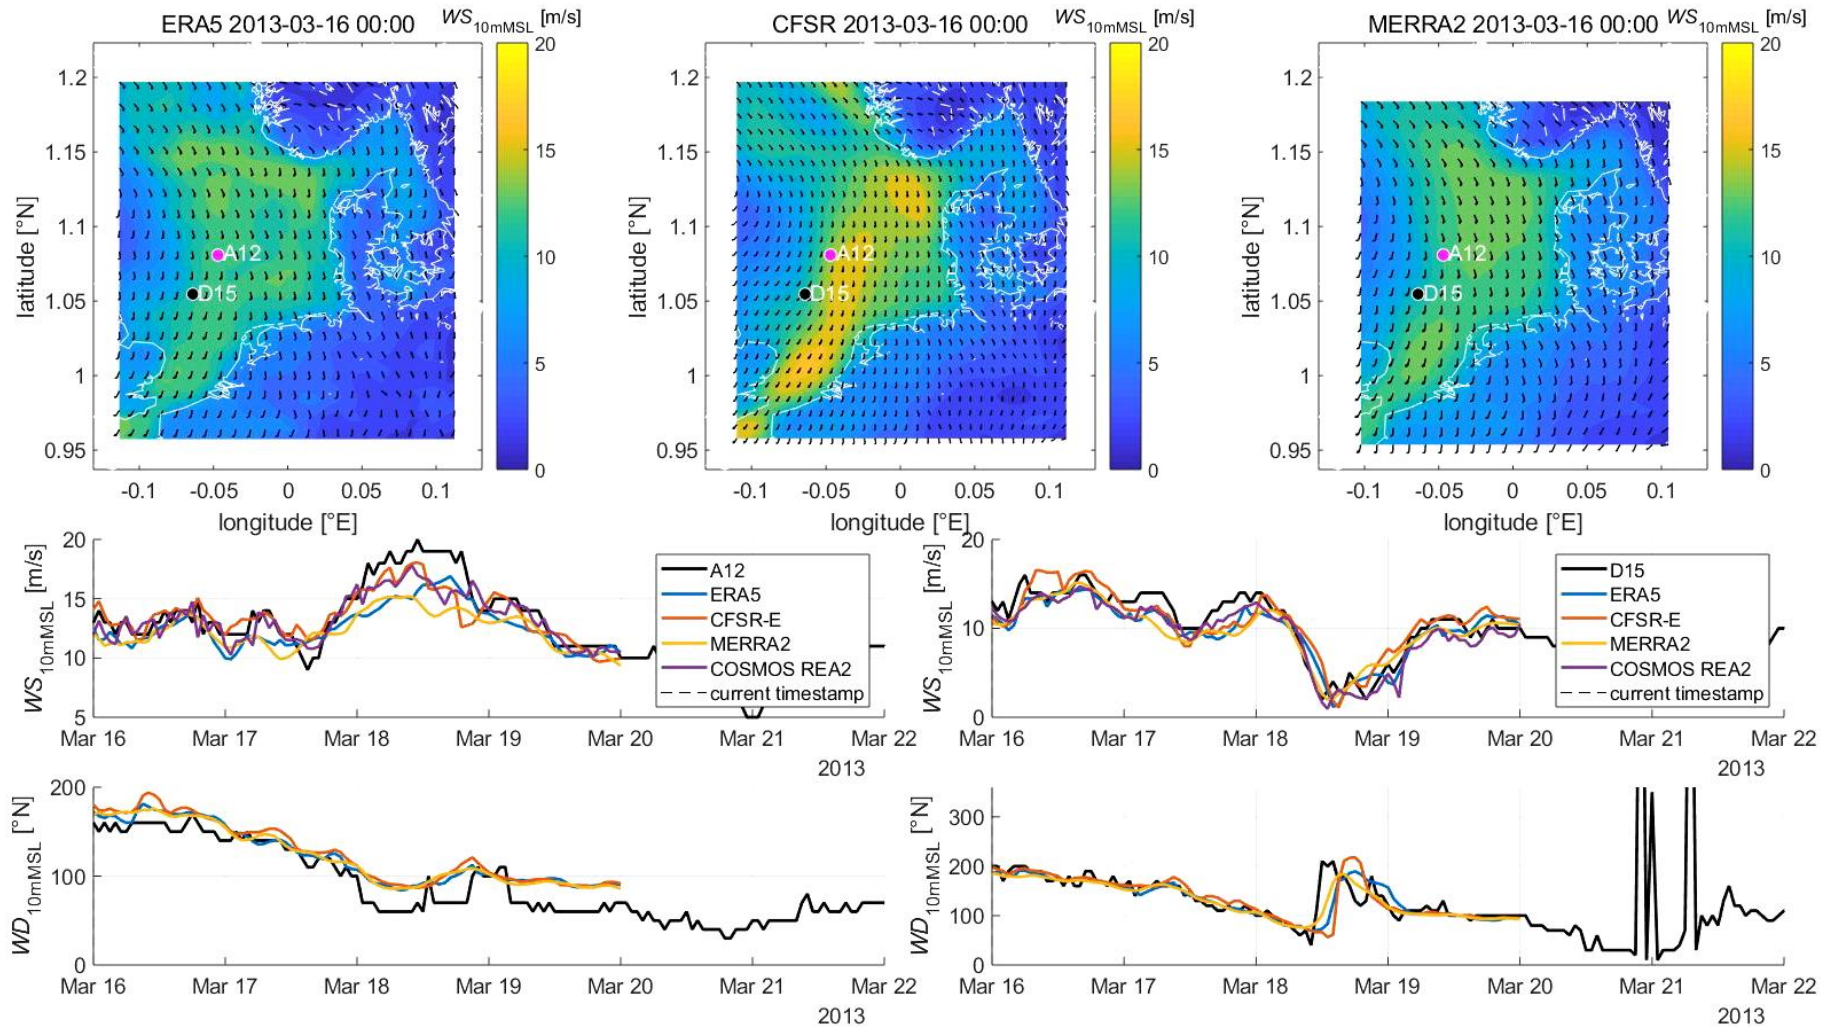

This happens for instance when the wind speed suddenly drops after a long-lasting storm.

Generally well captured by WRF-driven models, and not well captured when using reanalysis datasets.

However, these load cases are generally not design-driving, and they can be characterised conservatively.

# A medium storm that is hard to catch

# Wrap-up

## For Normal Wind Conditions:

- Best is to rely on detailed wind resource assessment (measurements + mesoscale).
- For that purpose, increased spatial resolution of the mesoscale model is not always key.
- ★ ➤ Recommended to focus instead on the parametrisation schemes and the orography/landuse input.
- ★ ➤ The model is very likely making an error – need to guess and assess uncertainty.

## For Normal Sea State:

- Spectral wave models driven with reanalysis data work satisfactorily.
- Always need to assess effect of land/sea mask.
- ★ ➤ Local wave models driven by higher fidelity wind data do not necessarily perform much better, but provide a hub height wind time series that requires only small adjustments -> increased fidelity.

## For Extreme and Severe Sea State:

- Advantage in using mesoscale time series compared to reanalysis.
- ★ ➤ Yet, the 10-minute extreme wind speed is out of reach for models.
